

Financial literacy in India remains low, and tax knowledge is its weakest component. A 2019 national survey found that 27 percent of adults were financially literate, with the poorest performance on tax and procedural questions. Young earners consequently face their first tax decisions with little preparation. The tools available to them divide along an unhelpful line: tax portals compute accurately but assume a vocabulary the first time filer does not possess, while general-purpose conversational assistants explain fluently yet have been shown in published benchmarks to make material errors on jurisdiction specific tax computation.

This paper presents a conversational platform for financial literacy and management, driven by a multi agent orchestrator. Through a single chat interface, a young earner can learn a concept, compute a figure under the applicable statute, and understand what that result means for their money. Three specialist agents handle teaching, computation and personal money management, and are separated by the capabilities each is permitted to use rather than by instruction alone. The platform follows a layered architecture in which a core layer manages the agents, the tools and the memory.

The governing constraint of the design is that the language model never originates a numerical value. It determines which calculation is required and phrases the outcome, while a deterministic rule engine reading a versioned rulebook produces every figure. Three properties follow without additional mechanism: each figure is traceable to the rule that produced it, results are reproducible irrespective of the model used, and the system continues to compute correctly when no model is available.
